

For the run function, I added an event listener to detect if button1 has been clicked. Once it has been clicked, the handleButton1Click function is run. This function will invoke the min_max function with the input being an array of the comma separated numbers entered by the user in the text box.

min_max works by first setting the min and max to the 1st value in the array. We then loop over all the subsequent elements of the array. If the element is smaller than min, we set it as the new min. If it is larger than max, we set it as the new max. These values are returned to its caller to be displayed on the html.
